CAD Design (Changes)

Simplified V-REP Model (Changes)

Creep Gait

Order of Legs in Creep Gait

Trot Gait

Camera

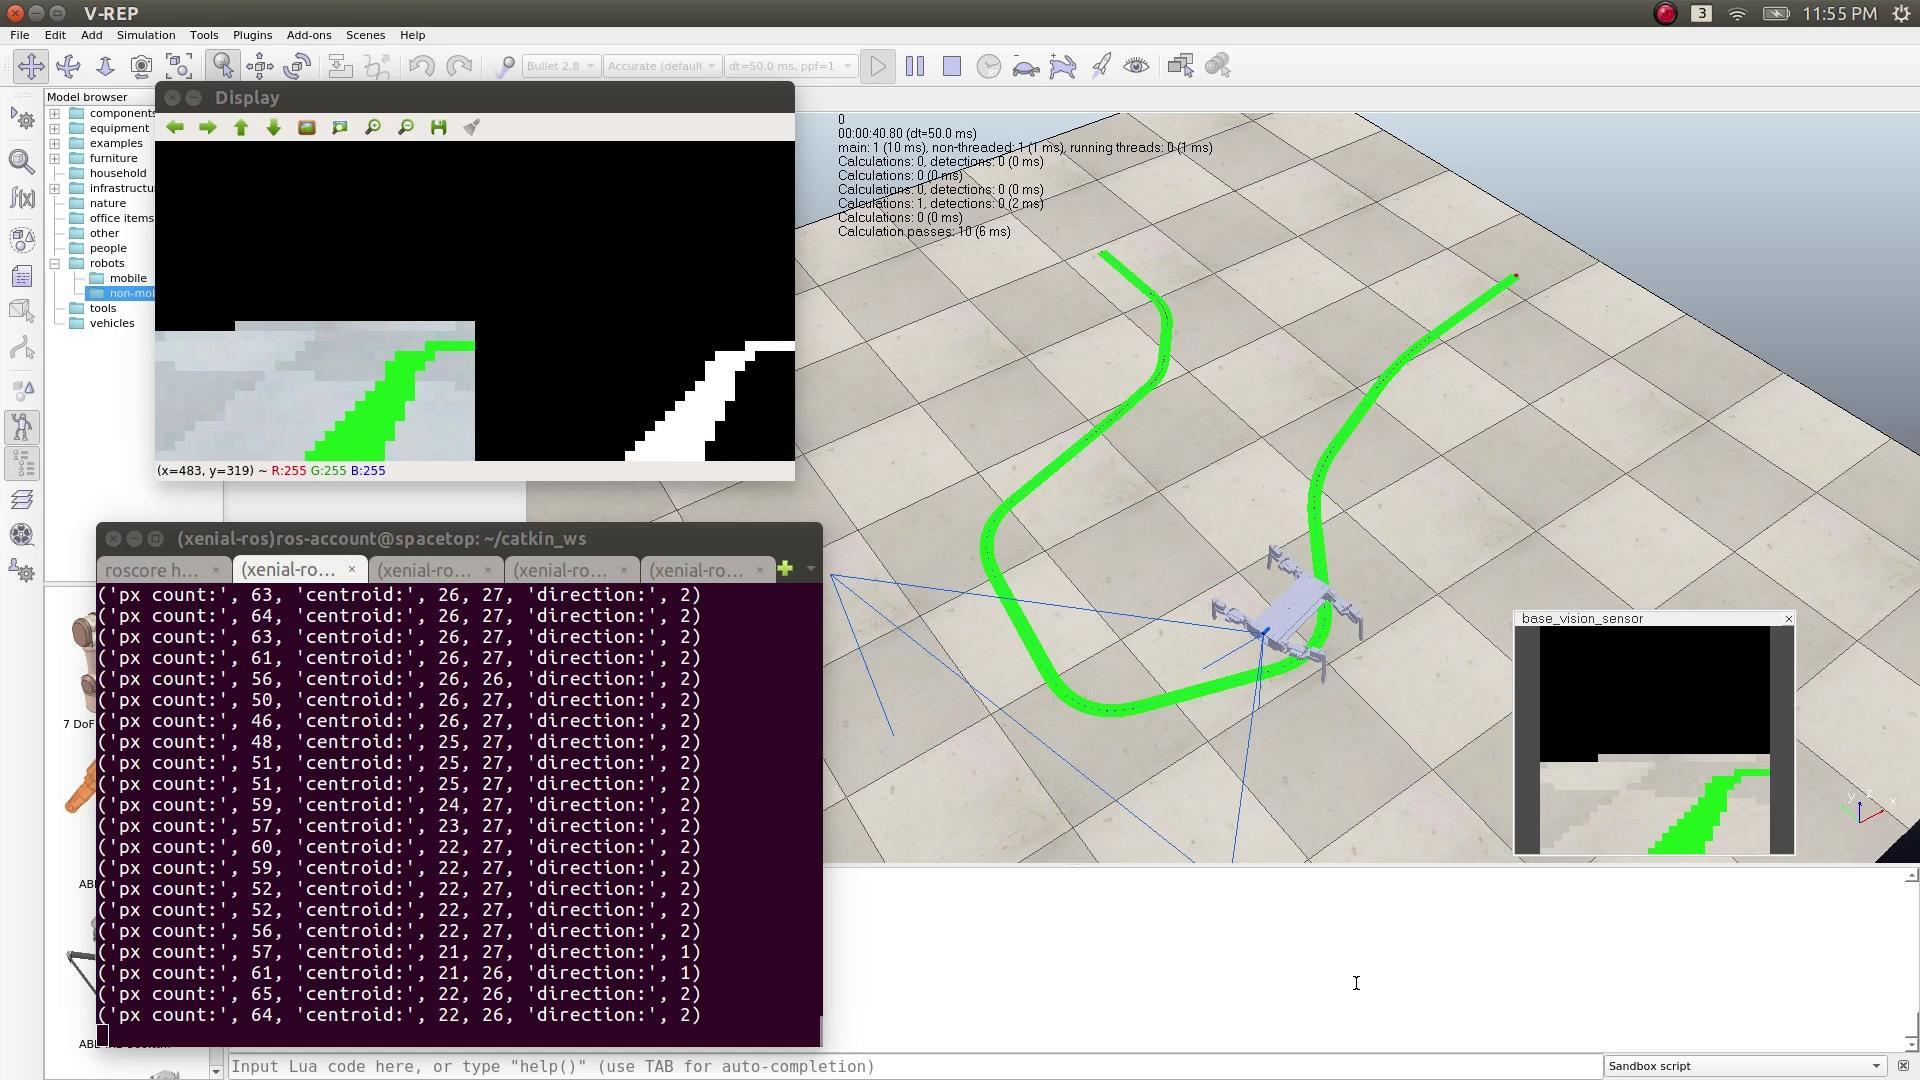

Camera properties:

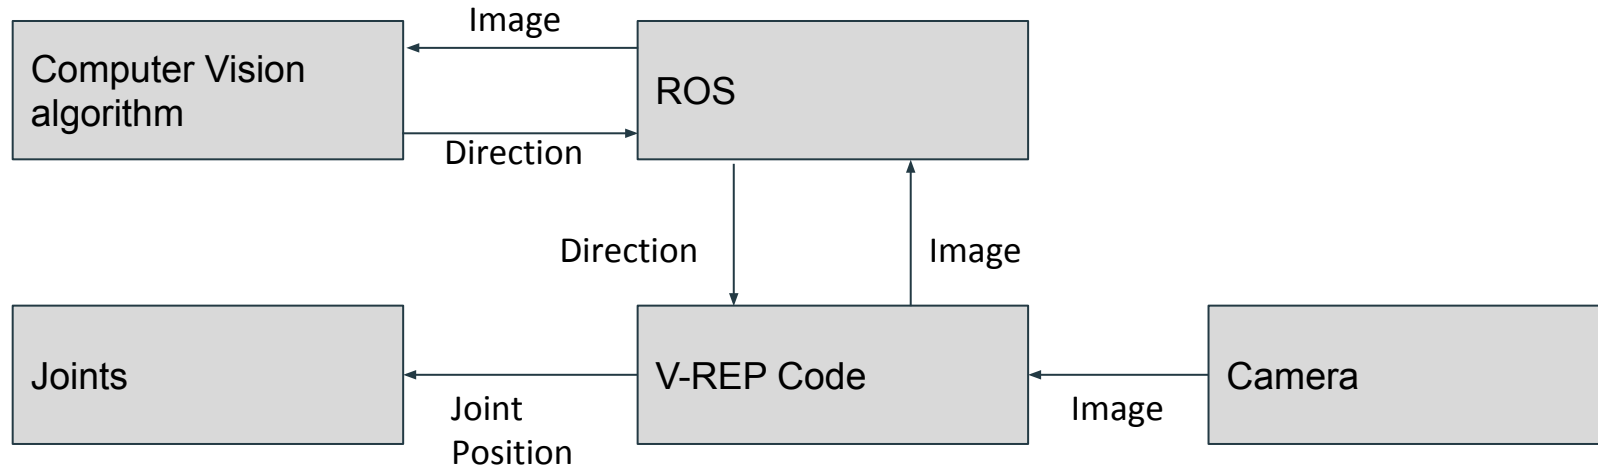

- Type: Perspective
- Resolution: 32x32
- FoV: 60°

Environment

Control System Overview

Low level instructions

The trot gait algorithm has been implemented in Lua on V-REP. The overall control system is a bang-bang controller. There are 4 high-level instructions the robot can follow:

- Move forward
- Turn right
- Turn left
- Stop

For moving forward, right and left the parameters of the trot gait are modified slightly. Then the corresponding joint angles are calculated and finally the target joint positions are set. For stopping, all joints are set to their default position.

Communication over ROS

The system has 2 ROS nodes - one is `vrep_ros_interface` (V-REP) and the other is `controller` (the computer vision program).

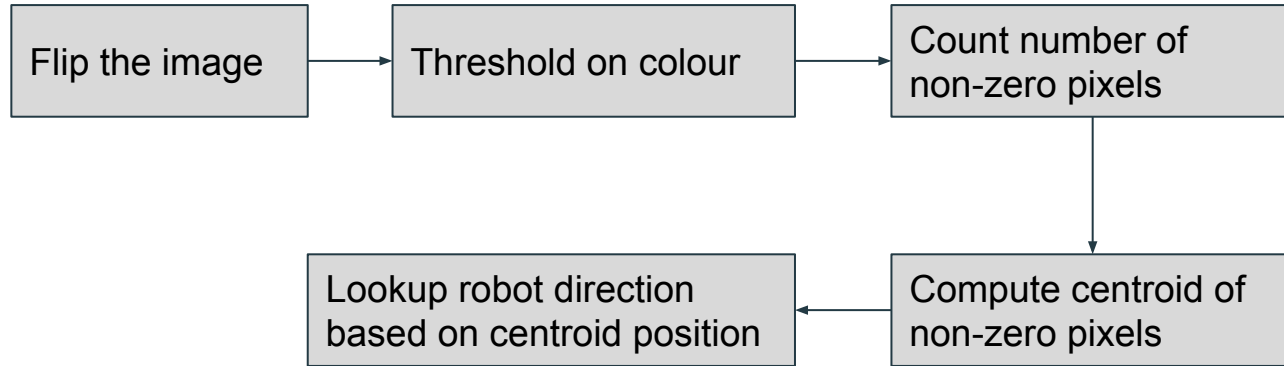

They communicate over 2 channels - `image` (to transfer the image captured by the camera) and `alg_ctrl` (to send a high level instruction back to V-REP).

`vrep_ros_interface` subscribes to `alg_ctrl` and publishes to `image`.
`controller` subscribes to `image` and publishes to `alg_ctrl`.
